### Adjustment of ER-Diagram

Based on the feedback we received for Milestone 1 and our discussions related to Milestone 2, we decided to slightly adjust our ER-Diagram:

- The entity Payment is no longer modeled as a weak entity. Further, we allow installment payments (e.g. clients can pay for their individualized trips with several payments), which leads to a 1:N relationship. This also implies that the amount of the payment can be different from the price of the trip.
- We added the attributes City and Country to the entity Activity. This allows us to know where an activity takes place. For simplicity, we decided to drop the attribute Contact from the entity Activity. The phone number of the activity provider is not essential in our simplified model.
- We moved the attributes Date and Number of Nights from the entities Activity, Transport and Accommodation to the relationships has\_activity, has\_transport and has\_accommodation, respectively. We opted for this adjustment, because Date and Number of Nights are the only things that might change, while all other attributes of these three entities cannot change between different trips (e.g. the address of a hotel always stays the same). This allows us to load data more efficiently into our database. Example: When we add a hotel to a trip, we only have to specify the trip and hotel ID, the start date and the number of nights in the relation has\_accommodation. But we don't have to specify the name or address of the hotel for each new trip which uses this hotel.

You find our adjusted ER-Diagram on the next page.
